

# Stacking

BY MG ANALYTICS

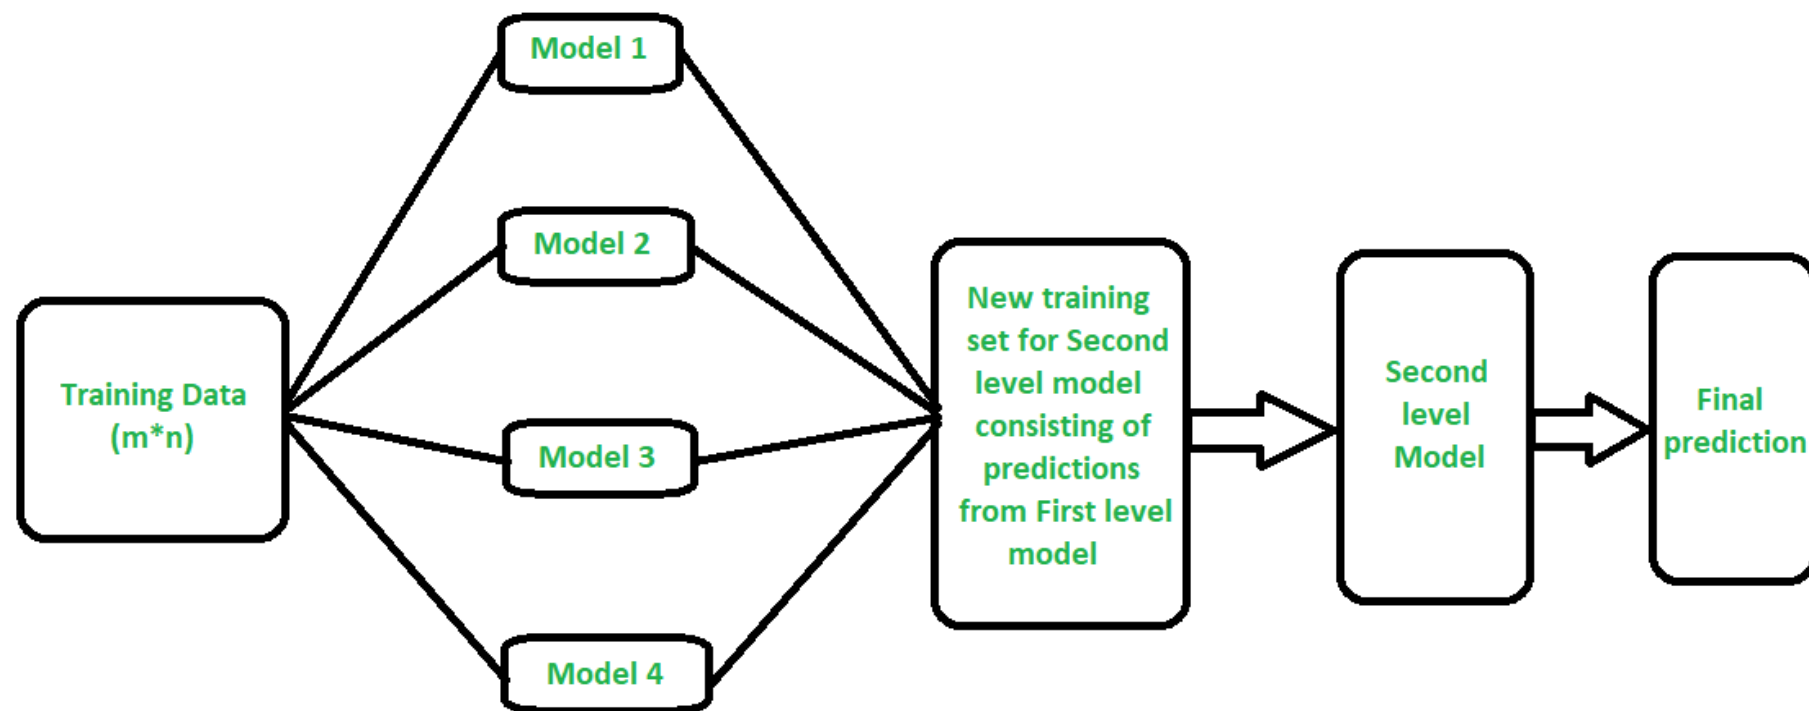

When to  
choose  
what??

- ▶ **Decrease**
  - ▶ **Variance** (bagging)
  - ▶ **Bias** (boosting)
  - ▶ **Improve predictions** (stacking).

# Stacking

- ▶ **Stacked** Generalization or “**Stacking**” for short is an ensemble machine learning algorithm.
- ▶ combining the predictions from multiple machine learning **models** on the same dataset.
- ▶ to explore a space of different models for the same problem.
- ▶ Learning with different types of models which are capable to learn some part of the problem, but not the whole space of the problem.

- ▶ Models to be stacked should be non linear in nature.
- ▶ The models are combine using a linear method.

# Process

- ▶ Initial training data ( $\mathbf{X}$ ) has  $m$  observations, and  $n$  features (so it is  $m \times n$ ).
- ▶ There are  $M$  different models that are trained on  $\mathbf{X}$  (by some method of training, like cross-validation) before hand.
- ▶ Each model provides predictions for the outcome ( $y$ ) which are then cast into a second level training data ( $\mathbf{X}^{(2)}$ ) which is now  $m \times M$ . Namely, the  $M$  predictions become features for this second level data.
- ▶ A second level model (or models) can then be trained on this data to produce the final outcomes which will be used for predictions.

# Cross Sampling

- ▶ Stacking uses a similar idea to k-folds cross validation to create **out-of-sample** predictions.
- ▶ if we were to use predictions from the M models that are **fit to all the training data**, then the second level model will be biased towards the best of M models.
- ▶ We alternately train the Models on k-1 folds and predict the out of box kth fold using this trained model.
- ▶ This allows the predictions to be out of sample and useful for training of next layer.
